## FORECASTING THE FLASHPOINTS

*Nicholas O. Stephanopoulos*

In *Spatial Diversity*,<sup>1</sup> I relied on 2005–2009 data from the American Community Survey (ACS) to analyze the congressional districts that were used in the elections of the 2000s. In this brief addendum, I employ more recent ACS data, covering the 2006–2010 period,<sup>2</sup> to analyze the congressional districts that recently have been drawn for the next decade’s elections. My findings should be a valuable resource for courts, litigants, scholars, and anyone else interested in the geographic makeup of America’s new congressional districts. The overall story is one of substantial continuity, but this headline masks an array of interesting subplots: for instance, the improvement of California’s district plan, the worsening of Maryland, North Carolina, and Pennsylvania’s, and the increase in the number of districts with highly heterogeneous African American populations.

### I. INDIVIDUAL DISTRICTS

To begin with, I selected the same ACS variables that I used in my earlier study,<sup>3</sup> again at the level of the Census tract,<sup>4</sup> and then carried out a nationwide factor analysis.<sup>5</sup> Not surprisingly, the results of this analysis were extremely similar to my prior findings. Eight composite factors again emerged, capturing 61.6% (as opposed to 60.9%) of the variance in the underlying data. Socioeconomic status was again the most important factor, again followed by urban/suburban location, Hispanic ethnicity, African American race, and Asian American race. Only with the final three factors were there any salient differences; age and white ethnic background switched places, while work in retail is now a more significant determinant of the last factor than agricultural employment.<sup>6</sup> As one might expect, Americans’ residential patterns barely changed with the passage of one additional year.

---

<sup>1</sup> Nicholas O. Stephanopoulos, *Spatial Diversity*, 125 HARV. L. REV. 1903 (2012).

<sup>2</sup> This data was released on December 8, 2011. See *2010 Data Release*, U.S. Census Bureau, [http://www.census.gov/acs/www/data\\_documentation/2010\\_release/](http://www.census.gov/acs/www/data_documentation/2010_release/) (last visited June 20, 2012).

<sup>3</sup> The only exception is that the latest ACS data release includes five occupation categories instead of six.

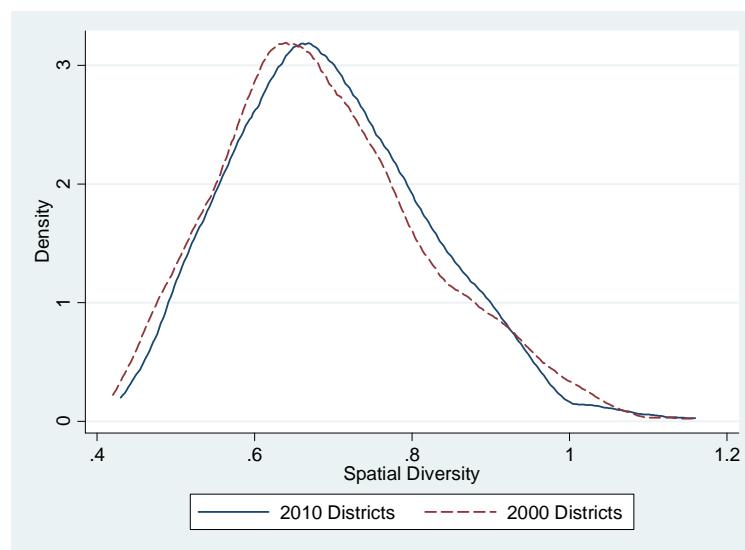

<sup>4</sup> The new ACS data is available for 2010 Census tracts, while the older data was available only for 2000 Census tracts.

<sup>5</sup> See *infra* app. tbl.1.

<sup>6</sup> And this difference in the final factor may well be the result of the omission of the Occupation–Farm/Fish category from the 2006–2010 ACS survey.

Next, I calculated spatial diversity scores for all of the newly drawn congressional districts.<sup>7</sup> These scores are listed in order from highest to lowest in Table 2 in the Appendix.<sup>8</sup> The new districts have a slightly higher mean (0.70 versus 0.69) and median (0.68 versus 0.67) than their predecessors, and their standard deviation is slightly lower (0.12 versus 0.13). As Figure 1 illustrates, there are also somewhat fewer new districts that are *highly* spatially diverse; the right tail of the new district distribution is located a bit below the right tail of the old distribution. Given the legal and democratic problems associated with high spatial diversity,<sup>9</sup> this is a positive (but relatively minor) development. Voter participation and legislative representation should be somewhat improved in the new districts, and somewhat fewer of them should be vulnerable to political gerrymandering or state community-of-interest challenges.

FIGURE 1: SPATIAL DIVERSITY DISTRIBUTIONS  
OF 2000S AND 2010S DISTRICTS

<sup>7</sup> Kansas's congressional district plan has been passed by one legislative chamber but is not yet final. New Hampshire's plan is still awaiting preclearance from the Department of Justice, while Texas's plan is still awaiting preclearance from a Washington, DC federal court. Arizona, Florida, Illinois, Maine, Maryland, Missouri, North Carolina, South Carolina, Texas, Washington, West Virginia, and Wisconsin's plans are still in litigation. See All About Redistricting, <http://redistricting.lls.edu/> (last visited June 20, 2012).

<sup>8</sup> See *infra* app. tbl.2.

<sup>9</sup> See Stephanopoulos, *supra* note 1, at 1941–48 (discussing participatory and representational harms of spatial diversity); *id.* at 1924–35 (discussing Supreme Court's apparent preference for spatially homogeneous districts in several doctrinal domains).

Among the most spatially diverse new districts, several are almost identical to the districts they replaced. For example, the most diverse district in the country, Illinois's new Seventh, traces nearly the same path through greater Chicago as did its predecessor, which was the most diverse district of the previous decade. Similarly, the nation's third-most diverse district, New York's new Tenth, joins Manhattan's west side with central Brooklyn in almost the same fashion as did its antecedent. On the other hand, some of the highly spatially diverse new districts are novel cartographic creations. For instance, the fourth-most diverse district in the country, California's new Thirteenth, is composed of the East Bay portions of two old districts. Likewise, the nation's eighth most diverse district, Pennsylvania's new Second, merges western Philadelphia with the Main Line suburbs; these two areas previously had belonged to different districts.

America's thirty most spatially diverse districts are located in fifteen different states.<sup>10</sup> California leads the pack with six, followed by Maryland with four, New Jersey and New York with three, and Illinois, Pennsylvania, and Texas with two. In the previous decade, California had *eleven* of the thirty most diverse districts, New York had four, and Illinois, Maryland, New Jersey, and Texas had two. The improvement of California's plan,<sup>11</sup> and the deterioration of Maryland and Pennsylvania's plans, are confirmed by the statewide statistics to which I turn next.

## II. STATE PLANS

At the state level, I first computed averages of the spatial diversity scores of each state's new districts.<sup>12</sup> By this relatively crude metric, Hawaii now has the country's most spatially diverse districts and Maine has the country's least diverse. Among the larger states, Maryland, California, and New Jersey have particularly diverse districts, while Minnesota, Wisconsin, and Missouri have particularly nondiverse districts. The difference between the least and the most diverse state is almost exactly the same as in the previous decade.

Raw averages are a relatively crude measure of spatial diversity because they are driven heavily by factors *other* than states' district-

<sup>10</sup> I examine the thirty most spatially diverse districts in each decade because this approximates the number of districts with spatial diversity scores above 0.90 — a useful threshold for an exceptionally high level of spatial diversity. The results are similar if somewhat more or fewer districts are considered.

<sup>11</sup> See generally Nicholas O. Stephanopoulos, *Communities and the Commission*, 23 Stan. L. & Pol'y Rev. (forthcoming 2012) (presenting more detailed data documenting the improvement of California's new commission-crafted plan).

<sup>12</sup> See *infra* app. tbl.3.

drawing choices — in particular, states' intrinsic levels of geographic heterogeneity and the numbers of districts that they possess. For states with at least five congressional districts (for which these calculations are more meaningful), I therefore regressed the raw averages against the intrinsic levels of heterogeneity as well as the natural logarithm of the number of districts in each state. I then determined the *regression residual* for each state, that is, the difference between the state's actual spatial diversity average and the average predicted by the regression. A positive residual indicates that a state's districts are more diverse than one would expect given the state's intrinsic heterogeneity and number of districts, presumably because of diversity-increasing district-drawing choices. Conversely, a negative residual means that a state's districts are less diverse than one would expect, presumably because of diversity-reducing district-drawing choices.<sup>13</sup>

According to this more sophisticated metric, as Figure 2 shows, the states with the worst new district plans (i.e., the plans with the highest regression residuals) include Maryland, Texas, and Connecticut. Connecticut's position on this list is unexpected since its plan was drawn by a court-appointed special master (though pursuant to a directive to modify the state's old plan as little as possible).<sup>14</sup> Maryland and Texas's rankings are more explicable. Maryland's plan was crafted by a single party's politicians and criticized by a federal judge for its unusually heterogeneous districts.<sup>15</sup> Texas's plan technically was designed by a federal court,<sup>16</sup> but only after the Supreme Court intervened to compel the court to be more deferential to the (highly partisan) districts originally enacted by the state's political branches.<sup>17</sup>

On the other hand, the states with the best new district plans (i.e., the plans with the lowest regression residuals) include New York, Wisconsin, Minnesota, and Virginia. While Wisconsin and Virginia's plans were passed by the political branches, New York and Minnesota's were drawn by courts on the basis of redistricting criteria that tend to promote spatial homogeneity, such as compactness, respect for

<sup>13</sup> For another example of regression residuals being used to analyze district plans, see Stephanopoulos, *supra* note 11 (manuscript at 19–21). See also Jia Wang et al., Measuring Country Performance on Health 6 (1999) (discussing use of regression residuals as performance measures).

<sup>14</sup> See Order Directing Special Master, In re Petition of Reapportionment Commission, No. SC 18907 (Conn. Jan. 3, 2012), available at <http://www.jud.ct.gov/external/news/18907/default.htm>.

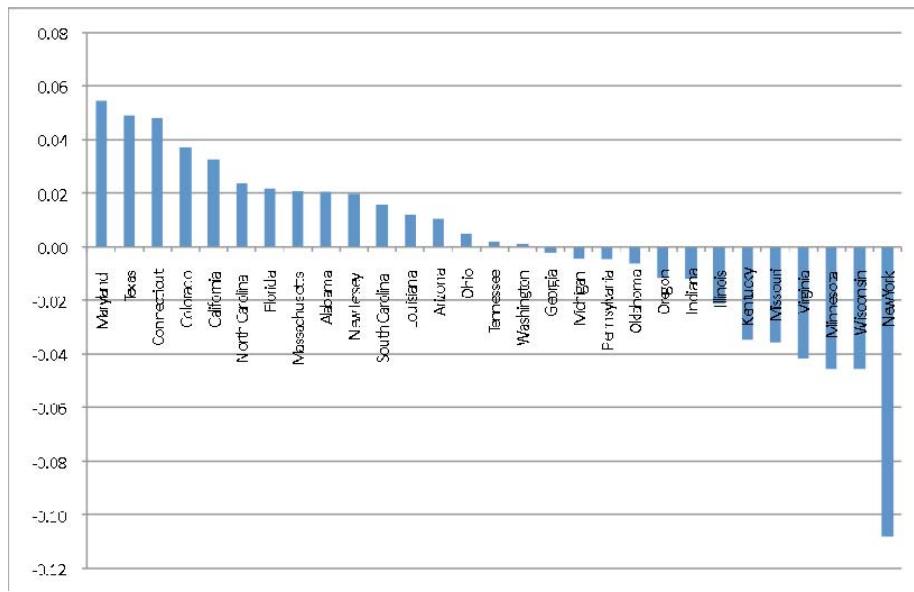

<sup>15</sup> See Fletcher v. Lamone, No. RWT-11cv3220, 2011 WL 6740169, at \*15–18 (D. Md. Dec. 23, 2011) (Titus, J., concurring); see also Nicholas Stephanopoulos, *The Answer to the Gerrymander*, Baltimore Sun, Jan. 9, 2012, at 15A.

<sup>16</sup> See Order, Perez v. Perry, No. SA-11-CV-360 (W.D. Tex. Feb. 28, 2012), available at <http://redistricting.lls.edu/cases-TX.php#TX>.

<sup>17</sup> See Perry v. Perez, 132 S. Ct. 934, 943–944 (2012).

political subdivisions, and preservation of communities of interest.<sup>18</sup> These states' strong performances therefore come as little surprise — though the sheer size of New York's negative residual, more than twice that of any other state, is somewhat startling.

FIGURE 2: 2010S STATE REGRESSION RESIDUALS

A related question is how states' plans *changed* between the 2000 and 2010 redistricting cycles. To investigate this issue, I calculated the difference between each state's 2000 and 2010 regression residuals (with a positive number indicating an increase in spatial diversity and vice versa). As Figure 3 illustrates, Maryland, North Carolina, and Pennsylvania experienced the largest residual increase in the country, suggesting that their plans worsened substantially. As in this cycle, politicians from the same party designed all three states' districts in the 2000s,<sup>19</sup> so it seems that this decade's line-drawers were simply more aggressive — and less attentive to underlying geographic realities — than their predecessors.

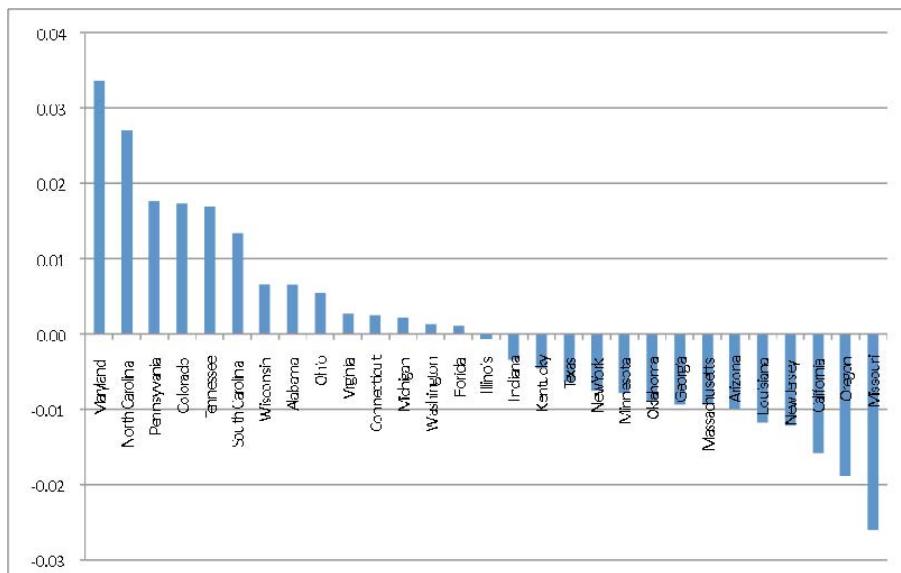

Conversely, Missouri, Oregon, and California experienced the largest residual decreases in the country, implying that their plans im-

<sup>18</sup> See *Favors v. Cuomo*, No. 11-CV-5632 (RR)(GEL)(DLI)(RLM), 2012 WL 928223, at \*4 (E.D.N.Y. Mar. 19, 2012); *Hippert v. Ritchie*, No. A11-152, 2012 WL 540828, at \*2 (Minn. Feb. 21, 2012) (opinion of Special Redistricting Panel).

<sup>19</sup> See Michael P. McDonald, *A Comparative Analysis of Redistricting Institutions in the United States, 2001–02*, 4 *State Pol. & Pol'y Q.* 371, 386–88 (2004).

proved significantly. Missouri and Oregon are two of the very few states whose political branches are not currently under the control of a single party.<sup>20</sup> It is unsurprising that divided government may result in more geographically sensible plans than a political configuration dominated by a single party.<sup>21</sup> As for California, it recently transferred authority over redistricting from the political branches to an independent commission that is required to prioritize the preservation of political subdivisions and communities of interest.<sup>22</sup> A sizeable rise in spatial homogeneity is exactly what one would expect from such a policy change.

FIGURE 3: CHANGES IN STATE REGRESSION RESIDUALS  
FROM 2000S TO 2010S

### III. HEAVILY MINORITY DISTRICTS

Finally, I examined the spatial diversity of the minority populations that are located within heavily minority districts (i.e., districts that are more than forty percent African American or Hispanic). I first ran na-

<sup>20</sup> See *Missouri*, All About Redistricting, <http://redistricting.lls.edu/states-MO.php> (last visited June 20, 2012); *Oregon*, All About Redistricting, <http://redistricting.lls.edu/states-OR.php> (last visited June 20, 2012).

<sup>21</sup> Cf. Andrew Gelman & Gary King, *Enhancing Democracy Through Legislative Redistricting*, 88 Am. Pol. Sci. Rev. 541, 552–53 (1994) (finding that bipartisan plans exhibit lower levels of partisan bias than partisan plans).

<sup>22</sup> See Stephanopoulos, *supra* note 11 (manuscript at 6–8).

tionwide factor analyses for (1) all Census tracts that are at least forty percent African American,<sup>23</sup> and (2) all tracts that are at least forty percent Hispanic.<sup>24</sup> Not unexpectedly, the results of these analyses were quite similar to my prior findings. In the analysis of the African American population, six composite factors again emerged, capturing 55.8% (as opposed to 54.2%) of the variance in the underlying data. Socioeconomic status was again the most important factor, and the only notable change was that the third and fourth factors, urban/suburban location and African American race, switched places. In the analysis of the Hispanic population, seven factors emerged instead of eight, capturing 60.0% (as opposed to 62.4%) of the data's variance. Urban/suburban location remained the most influential factor, while socioeconomic status and Hispanic ethnicity switched places, Asian American race moved up two spots, employment in construction fell two spots, and agricultural employment ceased to register.

Next, I calculated spatial diversity scores for the relevant minority populations within the heavily minority districts. These scores are listed in order from highest to lowest in Tables 6 and 7 in the Appendix.<sup>25</sup> The new African American districts have a somewhat higher mean (0.76 versus 0.74) and median (0.77 versus 0.76) than their predecessors, and their standard deviation is slightly lower (0.07 versus 0.08). As Figure 4 shows, there are also substantially more black populations in heavily black districts that are *highly* spatially diverse. The entire right side of the new district distribution is located above the right side of the old distribution, and it extends to levels of spatial diversity that were nonexistent in the previous decade. This is a worrisome development that suggests that, after the relative ceasefire of the 2000s,<sup>26</sup> the courts may soon be confronted with a spate of racial gerrymandering and racial vote dilution challenges.

Some of the districts responsible for the distribution's rightward shift are revised versions of heavily African American districts from the 2000s. For example, Maryland's new Fourth District, which contains the country's most spatially heterogeneous black population, includes the same section of central Prince George's County as the district it replaced, the old Fourth. However, the new Fourth also encompasses affluent African American areas in northern Prince George's County — which is why its black population's heterogeneity is noticeably higher. Similarly, Illinois's new Second District, like the

<sup>23</sup> See *infra* app. tbl.4.

<sup>24</sup> See *infra* app. tbl.5.

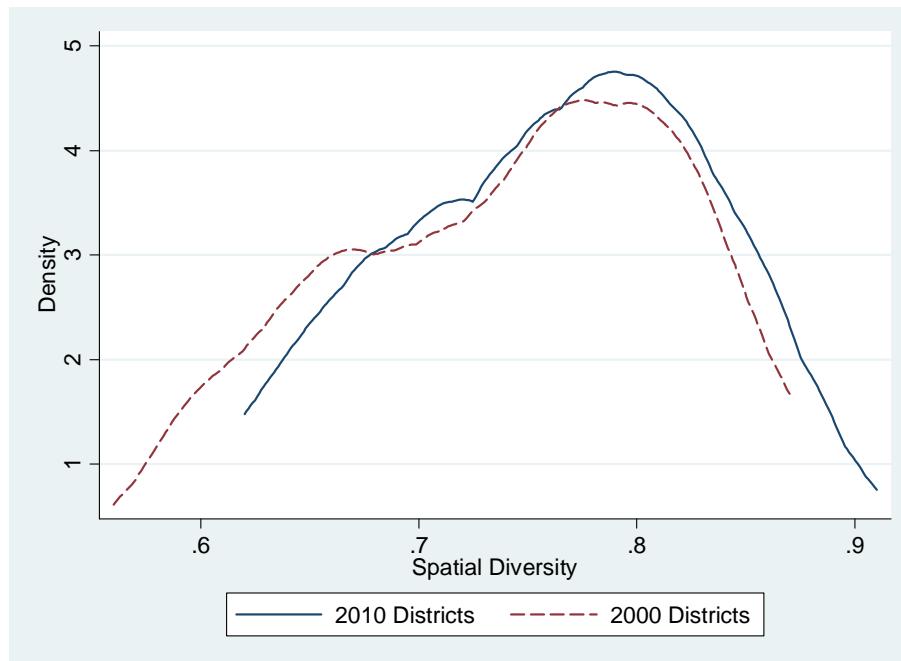

<sup>25</sup> See *infra* app. tbls.6–7.

<sup>26</sup> See Richard H. Pildes, *The Supreme Court, 2003 Term — Foreword: The Constitutionalization of Democratic Politics*, 118 Harv. L. Rev. 28, 67–68 (2004) (noting low level of racial gerrymandering litigation in the 2000s).

old Second, proceeds from Chicago's South Side into the city's southern suburbs. But the new Second's black population is more heterogeneous because it is less heavily urban and more evenly divided between city and suburb.

Conversely, several districts with highly varied African American populations have no real antecedents in the previous cycle. Texas, for instance, did not have a single district in the 2000s that was at least forty percent black. It now has two: the new Eighteenth, which corrals African American neighborhoods throughout Houston, and the new Thirtieth, which does the same in Dallas. Likewise, Louisiana's old Second District was confined almost exclusively to New Orleans, while the new Second absorbs black communities up the Mississippi River all the way to Baton Rouge. And Michigan's new Fourteenth District, unlike the old Thirteenth, reaches northwest from Detroit into the middle-class African American suburb of Southfield.

FIGURE 4: SPATIAL DIVERSITY DISTRIBUTIONS OF 2000S AND 2010S HEAVILY AFRICAN AMERICAN DISTRICTS

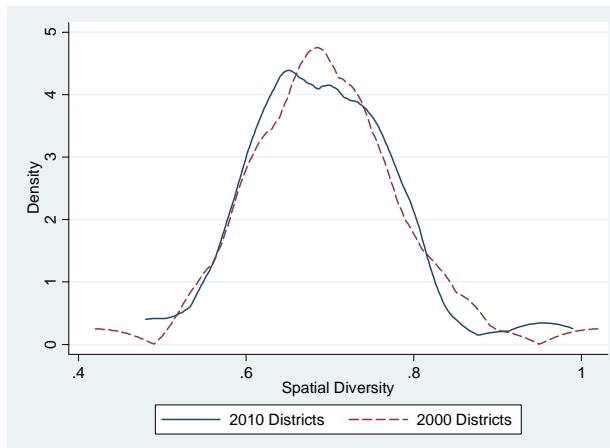

Turning to the new heavily Hispanic districts, they have almost exactly the same mean (0.69 versus 0.69), median (0.69 versus 0.70), and standard deviation (0.09 versus 0.10) as their predecessors. As Figure 5 illustrates, the overall shapes of the two distributions are very similar as well. At the high spatial diversity end, in particular, the right tail of

the new distribution falls sometimes below and sometimes above the right tail of the old distribution; it is not obviously any better or worse. Accordingly, there is no reason to expect this decade's heavily Hispanic districts to be in any greater legal jeopardy than the districts they replaced.<sup>27</sup>

With respect to specific districts, Florida's new Twenty-Seventh District contains the country's most spatially heterogeneous Hispanic population, just as did its antecedent, the old Eighteenth. The new Twenty-Seventh's Hispanic population, however, is somewhat more homogeneous because it no longer includes Miami Beach, but rather extends deeper into Miami's western and southwestern suburbs. On the other hand, Florida's new Twenty-Fifth District, which contains the country's second-most heterogeneous Hispanic population, scores a bit worse than the districts it replaced, the old Twenty-First and Twenty-Fifth. The explanation is that the new Twenty-Fifth is not limited to suburban Miami, but instead stretches through the interior almost all the way to the Gulf Coast. Among other districts with especially heterogeneous Hispanic populations, California's new Fifty-First resembles its predecessor, the old Fifty-First, but encompasses more of central San Diego; Texas's new Twentieth reaches west from San Antonio instead of veering east like the old Twentieth; and Texas's new Thirty-Fifth, a long tentacle connecting Hispanic communities in San Antonio and Austin, is an entirely new creation.

FIGURE 5: SPATIAL DIVERSITY DISTRIBUTIONS OF 2000S AND 2010S HEAVILY HISPANIC DISTRICTS

<sup>27</sup> Though it is worth noting that two heavily Hispanic districts, Florida's new Twenty-Seventh and Twenty-Fifth, contain minority populations that are more heterogeneous than those in any heavily African American district.

## CONCLUSION

In summary, America's newly drawn congressional districts present a mixed picture with respect to spatial diversity. On the positive side of the ledger, there are somewhat fewer districts that are highly spatially diverse, several states improved their districts substantially (most notably California), and heavily Hispanic districts grew no more heterogeneous despite the increase in the country's Hispanic population. On the negative side, the plans of several large states worsened significantly (e.g., Maryland, North Carolina, Pennsylvania), other large states' plans remained problematic (e.g., Texas), and there was a troublesome uptick in the heterogeneity of black populations in heavily black districts.

One lesson from these developments is that the identity of the line-drawing authority does seem to matter. States in which a single party controlled redistricting tended to experience increases in the spatial diversity of their plans. But states in which control was divided, or in which a court or commission designed the plan, tended to undergo decreases.<sup>28</sup> Similarly, the states with the biggest increases in districts with highly heterogeneous black populations were Illinois (under single-party control) and Texas (where a court was forced to defer to the political branches' choices).<sup>29</sup> Texas was also the only state to have substantially more districts with highly heterogeneous Hispanic populations, while California (with its independent commission) was the only state to see a decrease along this dimension.<sup>30</sup> Not unsurprisingly, partisan actors appear to craft the districts that are least attentive to underlying geographic realities — and most likely to violate the law — while the record of other line-drawing authorities is noticeably better.

<sup>28</sup> In particular, a two-sample t-test ( $t = 2.79$ ;  $p = 0.005$ ) indicates that there was a statistically significant difference between the regression residual changes in single party-control states and all other states.

<sup>29</sup> Illinois went from one heavily African American district with a spatial diversity score above 0.80 to three; Texas went from zero such districts to two.

<sup>30</sup> Texas went from one heavily Hispanic district with a spatial diversity score above 0.75 to three; California went from five such districts to four.
